ABSTRACT

Lightweight concrete (LWC) is a kind of concrete that made of lightweight aggregates or gas bubbles. These aggregates could be natural or artificial, and expanded polystyrene (EPS) lightweight concrete is the most interesting lightweight concrete and has good mechanical properties. Bulk density of this kind of concrete is between 300-2000 kg/m³. In this paper flexural strength of EPS is modeled using four regression models, nine neural network models and four adaptive Network-based Fuzzy Interface System model (ANFIS). Among these models, ANFIS model with Bell-shaped membership function has the best results and can predict the flexural strength of EPS lightweight concrete more accurately.

Keywords: EPS concrete; silica fume; flexural strength; modeling; regression; neural network, ANFIS.

Received: 20 August 2018; Accepted: 25 November 2018

1. INTRODUCTION

Concrete is one of the most widely used materials in construction industry. The main reason that makes concrete one of the popular material in building construction is its mechanical properties and its low cost (Maslehuddin et al. 2018; Traore et al. 2018). Economically, the weight of concrete is one of the most factors. Normal weight concrete (NWC) has relatively high unit

†E-mail address: sobhani@bhrc.ac.ir (J. Sobhani)
weight and has a bulk density ranging between 2200-2600 kg/m$^3$. In order to reduce the unit weight of concrete, lightweight aggregates could be used, and the concrete which made of these kind of aggregates, called lightweight concrete (LWC). LWC has a bulk density ranging between 300-2000 kg/m$^3$ (Maslehuddin et al. 2018; Aslam et al. 2017).

Lightweight concrete has been used for more than 80 years (Jafari and Mahini 2017). Because of its advantages, it is the most interesting field of researchers. These advantages including lower cost, better thermal performance, fire and frost resistance, cost-efficiency balance, sound absorption and etc. Because of lower density of LWC, lighter-weight structures could be produced (Aslam et al. 2017; Shafigh et al. 2018; Kwon and Mun 2018). Lightweight concrete has many applications including multi-storey buildings, concrete bridges, offshore oil platforms, and etc. (Jafari and Mahini 2017).

Lightweight concrete can be produced by:

i. Utilizing natural or artificial aggregates. Natural aggregate such as pumice, diatomite, volcanic cinders, scoria, tuff and artificial aggregate such as Oil-palm-boiler clinker (OPBC), clay, shale, slate, perlite. This type of LWCs are made in factories

ii. Using plastic granules instead of normal aggregates such as expanded polystyrene (EPS), polyurethane and etc.,

iii. Adding gas agent which produce gas in the alkaline environment of concrete such as aluminum powder or foaming agents (Maslehuddin et al. 2018; Aslam et al. 2017; Shafigh et al. 2018; Sadrmomtazi et al. 2012; Suseno et al. 2018).

Among these types of lightweight concrete, the one produced by expanded polystyrene with millimeter-size is more interesting than other types; because it is expected that structural elements fabricated on construction site. Also this kind of aggregate can be easily merged into concrete or mortar and create LWC (Bouvard et al. 2007; Liu and Chen 2014).

EPS lightweight concrete is a kind of new lightweight concrete that has good mechanical properties. First use of EPS was at 1973 by Cook (Liu and Chen 2014).

Strength properties, water absorption, shrinkage and electrical resistivity of EPS concrete containing silica fume and rice husk ash were experimentally studied by Sadrmomtazi et al. and the results showed a potential use of EPS beads for producing structural grade, moderate strength grade and insulating lightweight concrete [Sadrmomtazi et al. 2012]. Moreover, in 2013, Sadrmomtazi et al., modeled the compressive strength of EPS lightweight concrete using regression, neural network and ANFIS.

Despite a number of research studies on the different properties of EPS concrete, it has rarely investigated modeling their flexural strength properties. In this regard, the aim of this paper is to modeling the flexural strength of EPS lightweight concrete. Regression, neural network and ANFIS are the three methods used in this paper. Five regression, nine neural network and four ANFIS models were trained and tested. Before modeling, data were normalized to prevent the saturation problems. Finally, the results were compared to find the best model.

2. MODELING METHODS

2.1 Regression modeling

Regression Modeling is a tool which analysis the relationship between a response parameter (dependent variable) and one or more input parameters (independent variables). There are two types of regression: Linear and Nonlinear. In linear regression modeling, the aim is to fit
a linear equation between parameters, and in nonlinear regression modeling, the aim is to fit a nonlinear equation. In this paper, the general form of regression is

\[ y = f(\alpha_i \times x_i) \quad (1) \]

where \( f \) is the linear/nonlinear regression function, \( y \) is the dependent variable, \( x_i \) are the independent variables, and \( \alpha_i \) are the constant coefficients of the model (Sobhani et al. 2010).

The main goal of regression modeling is to find a function (linear or nonlinear) which has the best fitting.

2.2 Artificial neural network model

Artificial Neural Network (ANN) is an artificial intelligence-based method that provides a nonlinear relationship between input and output variables (Mannigård et al. 2018). Neural network is composed of simple elements. These elements are inspired by biological nervous system. ANN has a powerful ability in image process, regression, and etc. ANN consists of many processors which called processing elements (PE) or neurons, an input layer, one or more hidden layers (HLs) and one output layer. The layers between the input and output layer are called hidden layers and there is no direct link between input and output layers. The neurons receive the signals from input, process them through algorithms, biases and weights. The weights between the layers are selected randomly and during the processing, they didn’t change. But in each cycle, they change to obtain the best performance. The efficiency of this model depends on the quality and quantity of data (Sobhani et al. 2010; Cao et al. 2018; Schmidhuber 2015; Heidari et al. 2018).

In order to use a neural network, it’s necessary to specify some specifications, such as the number of layers, training algorithm, activation function, propagation rules and etc.

2.2.1 Training algorithm

Levenberg-Marquardt back-propagation algorithm is often the fastest back-propagation algorithm for training feed-forward neural networks. This algorithm is an approximation to Newton’s method. Newton's method is faster and more accurate near an error minimum, so the aim is to shift toward Newton's method as quickly as possible (Hagan and Menhaj 1994; Mathworks (1) 2017).

2.2.2 Propagation rules

For a multilayer model the propagation rule is the weighted sum and it is defined as:

\[ \sum_{i=1}^{n} w_{ij} x_i \quad (2) \]

where \( w_{ij} \) is the weight that connects PE \( i \) in the input layer to PE \( j \) in the hidden layer, \( x_i \) is the output from PE \( i \) in the input layer and \( n \) is the number of PEs. If there is bias in PE eq. 2 turned into (Villarrubia et al. 2018)
\[ \sum_{i=1}^{n} w_{ij} x_i + b \] (3)

Fig. 1 shows the architecture of artificial neural networks. As shown in this figure, ANNs consist of Inputs, training algorithm, activation function, propagation rule and output.

2.3 Adaptive network-based fuzzy interface system (ANFIS)

ANFIS is hybrid of neural network and fuzzy logic system for modeling the complex systems and it was first introduced by Jang. ANFIS uses a set of IF-THEN fuzzy rules to act like human reasoning style (Sobhani et al. 2010; Yuan et al. 2014). It has the benefits of both artificial neural network (ANN) and fuzzy systems. Particularly it has used in engineering applications, where classical methods fail or they are too complicated to be used (Vakhshouri and Nejadi 2017).

Type of membership functions and number of epochs are important factors in fuzzy logic system to create a model by minimum error size (Vakhshouri and Nejadi 2017). A membership function (MF) is a curve that defines how each point in the input space is mapped to a membership value (or degree of membership) between 0 and 1 (Mathworks 2017).

The architecture of an ANFIS model with two input variables is shown in Fig. 2. For simplicity of illustration only two inputs \((x, y)\) and one output \(f\) are considered in this figure.

Figure 1. Architecture of ANN

Figure 2. The architecture of ANFIS model
The function of each layer are described as (Sobhani et al. 2010; Yuan et al. 2014):

Layer 1: The first layer is the fuzzy layer. Every node in this layer is an adaptive node with a node function of

\[ O^1_i = \mu_{A_i}(x) \]  
(4)

where \( x \) is the input to node \( i \), and \( A_i \) is the linguistic label associated with this node function.

Layer 2: Every node in this layer is a circle node labeled \( \Pi \), which multiplies the incoming signals and sends the product out. For instance

\[ O^2_i = w_i = \mu_{A_i}(x) \times \mu_{B_i}(x), \quad i = 1,2 \]  
(5)

Layer 3: Every node in this layer is a circle node labeled \( N \). The ith node calculates the ratio of the ith rule’s firing weight to the sum of all rule’s firing weights:

\[ O^3_i = \bar{w}_i = \frac{w_i}{\sum w_i}, \quad i = 1,2 \]  
(6)

Layer 4: Every node in this layer is an adaptive node with a node function:

\[ O^4_i = \bar{w}_if_i, \quad i = 1,2 \]  
(7)

where \( \bar{w}_i \) is the output of layer 3, and \( f_i = p_i x + q_i y + r_i \) where \( \{p_i, q_i, r_i\} \) is the parameter set.

Layer 5: The signal node in this layer is a circle node labeled \( \sum \), that computes the overall output as the summation of all incoming signals

\[ O^5_i = \sum \bar{w}_i f_i = \sum w_i f_i / \sum w_i, \quad i = 1,2 \]  
(8)

There are five layers in this model: input, input membership function, rule, output membership function, and output.

3. MATERIALS AND MIXTURE DESIGN

3.1 Materials
The materials used to produce the lightweight concrete is described below:

3.1.1 Cementitious materials and fillers
In this study, the Portland cement (ASTM C150 (ASTM C150 2003)) as the main material and silica fume (SF) and rice hush ash (RHA) as the fillers were used. The chemical compositions and properties these materials are reported in Table 1.

3.1.3 Fibers and EPS beads

Moreover, the EPS beads were used as artificial lightweight aggregates in order to decrease the density of concrete. The size of 85% of EPS beads were about 3.5 mm.

In addition to the EPS beads, polypropylene (PP) fibers were used to improve the toughness of EPS lightweight concrete. The properties of PP fibers are presented in Table 3.

3.2 Mixture design

Twelve concrete mixtures were utilized with different composition of raw materials and water to cementitious materials ratio as summarized in Table 4.
4. DATA COLLECTION

The flexural strength of EPS lightweight concrete for four percentage of EPS, five percentage of PP, three weights of cement were reported in Table 4. Silica fume and rice hush ash were used 10 wt. % and 20 wt. %, respectively. EPS concrete specimens were prepared in the standard condition.

According to Table 1, cubic specimens of EPS concrete were produced and the database was created. These specimens were cured for 28 days. Then, according to ASTM C330 (ASTM C330 2003).

75 data records of EPS concrete Flexural strength at 28 days were gathered for database. 60 of these records were randomly utilized for training and the rest of them for testing the models. The structure of input-output of the modeler system was schematically shown in Fig. 3. In this Figure, the input parameters are (i) cement (C), (ii) silica fume (SF), (iii) water (W), (iv) fine aggregates (FA), (v) coarse aggregates (CA), (vi) expanded polystyrene beads (EPS), and (vii) Polypropylene fibers (PP) by weight per unit volume of concrete. Moreover, Table 5 summarizes the range of input and output of total data used for modeling purposes.

5. PREPROCESSING OF DATA

To prevent the saturation problem and consequently the low rate of the training [10], in neural network with log-sigmoid activation function it is important to normalize the data into a proper range. In this paper, the following function converts the real input data into the proportional values in the range of [0.1, 0.95]:

\[
out = 0.1 + (0.95 - 0.1) \times \frac{in - in_{min}}{in_{max} - in_{min}},
\]

(9)

where \(out\) is the normalized value, \(in\) is the rough input, \(in_{max}\) and \(in_{min}\) are the maximum and minimum of rough input, respectively. Clearly, by inversing the eq. 9, the values of model results could be converted to the real range.

6. MODELING PERFORMANCE CRITERIANS

To evaluate the performance of models, root means square (RMS), correlation factor (CF) and non-dimensional error index (NDEI) should be calculated for all models and then compared to each other. The model which has the lower RMS and the higher CF, is the best model.

6.1 Root means square

Root Means square is calculated by the following equation:

\[
RMS = \sqrt{\frac{1}{n} \sum_{i=1}^{n} (x_{rt} - x_{pt})^2}
\]

(10)
where \( n \) is the total number of samples, \( x_{ri} \) and \( x_{pi} \) are the real (experimental) and predicted values for the \( i \)th sample, respectively.

6.2 Correlation factor
Correlation Factor is calculated by the following equation:

\[
CF(x_r, x_p) = \frac{\text{cov}(X_r, X_p)}{\sqrt{\text{cov}(X_r, X_r) \ast \text{cov}(X_p, X_p)}}
\]  
(11)

where

\[
X_r = (x_{r1}, x_{r2}, ..., x_{rn}), \quad X_p = (x_{p1}, x_{p2}, ..., x_{pn})
\]  
(12)

and

\[
\text{cov}(X_r, X_p) = E[(X_r - \mu_r)(X_p - \mu_p)]
\]  
(13)

where

\[
\mu_r = E(X_r), \quad \mu_p = E(X_p)
\]  
(14)

where \( E \) is the mathematical expectation.

6.3 Non-dimensional error index
Non-dimensional error index can be calculated using:

\[
NDEI = \frac{\sqrt{\frac{1}{n} \sum_{i=1}^{n} (x_{ri} - x_{pi})^2}}{\sigma(x_r)}
\]  
(15)

where \( \sigma(x_r) \) is the standard deviation (Sobhani and Najimi 2014).

7. RESULTS AND DISCUSSION

In this paper, three types of modeling include regression, neural network, and ANFIS were used. For implementing these models, Matlab software was used.

7.1 Linear and nonlinear regression modeling
Four regression models proposed. These models are presented in Table 6. The calculated coefficients \( (\alpha_i) \) of these models are demonstrated in Table 7.

According to Fig. 4 and Table 8, model R2 is the best regression model, because it has the lowest RMS and highest CF. This model predicts the flexural strength of EPS concrete with RMS of 0.4150, 0.4166 and 0.4082 for training set, testing set and checking set, respectively. The CF values for training set, testing set and all data, according to model R2, are 0.9714, 0.9649 and 0.9667, respectively. The values of NDEI for training set, testing set and checking set in model R2 are 0.2354, 0.2796 and 0.2541, respectively.

The neural network models were trained by 60 data and tested by 15 data. Matlab software and its neural network tools were used to train the NN models.

The architectures and performance of neural network models are summarized in Table 10. First number in model name indicates the number of processing elements in hidden layer 1 and second number indicates the number of processing elements in hidden layer 2. According to Table 10, NNM34 has the best performance (lower RMS, lower NDEI highest CF). RMS values of this model are 0.1317, 0.2138 and 0.0842 for training set, testing set and checking data, respectively. CF values of this model are 0.9972, 0.9899 and 0.9987 for training set, testing set and checking data, respectively. The values of NDEI are 0.0747, 0.1436 and 0.0524 for training data, testing data and checking data, respectively.

As mentioned before NNM34 is the best model for neural network modeling, so experimental results versus modeling results for NNM34 is shown in Fig. 6. The horizontal and vertical axis represents the modeling results and experimental results, respectively. Accumulating more points near the diagonal line, represents better performance for the model.
7.3 ANFIS model

Similar to neural network, the ANFIS model use 7 inputs (i.e. C, SF, W, FA, CA, EPS and PP) and one output (i.e. FS). In this paper four types of membership function (MF) were used. These membership functions are Triangular, Trapezoidal, Bell-shaped and Gaussian. The formula and graphs of these MFs are shown in Table 11.

The ANFIS models were trained by 60 data and tested by 15 data. 100 epochs were specified for training process to assure that minimum error was gained. Also 15 data were chosen randomly among training and testing data as checking data.

The results of these ANFIS models were shown in Table 12. According to this table, all models have good performance, but the model with Bell-shaped membership function has the best performance for testing and checking data, so ANF-Bell is the best model. The RMS values of this model are 2.48e-4, 0.4494 and 0.2192 for training data, testing data and checking data, respectively. The values of CF of this model for training data, testing data and checking data are 1.0000, 0.9727 and 0.9915, respectively. Also the values of NDEI are 1.41e-4, 0.3018 and 0.1364 for training data, testing data and checking data, respectively.

Comparison of experimental results and ANF-Bell model is shown in Fig. 7.

In this paper, flexural strength of EPS lightweight concrete were modeled using regression, artificial neural network and ANFIS model. 75 data were made experimentally and among these data, 60 data were randomly selected to train the models and 15 data were used to test the proposed models. Four regression models, five neural network models and four ANFIS model were trained and the following results were obtained as follows:

- Among the four regression models (e.g. linear, pure quadratic, power and fractional) pure quadratic model has the best performance with lower RMS and higher CF.
For neural network models, the optimal number of PEs in HLs should be found. Among the nine neural network models, NNM34 has the best result, so the optimal number of PEs in HL1 is 3 and in HL2 is 4.

For ANFIS models several membership function were trained and among these MFs, Bell-Shaped MFs has the best results.

Among all regression, neural network and ANFIS models, Bell-shaped membership function of ANFIS model has best performance and could predict the Flexural Strength of EPS lightweight concrete better than other models.
